

Figure 13. Endogenous peroxidase is not a major source of nonspecific staining in tissues. Sections of a kidney incubated with chromogen without (A) and with (B) preincubation in hydrogen peroxide. Only weak nonspecific staining is present in red blood cells (arrow) in (A) compared to no staining in (B). Similarly, staining sections of spleen (C) and liver (D) without preincubation in hydrogen peroxide produces weak nonspecific staining in red blood cells (arrows).
